LLM **PROBLEMS**

1. Hallucinated answers

- LLMs predict plausible "completions." These are often factually incorrect.

LLM **PROBLEMS**

1. **Hallucinated answers**
   - LLMs predict plausible "completions." These are often factually incorrect.
2. **Stale training data**
   - It takes a long time to train an LLM and that means that the information they learn is often several years old.

LLM **PROBLEMS**

1. **Hallucinated answers**
   - LLMs predict plausible "completions." These are often factually incorrect.
2. **Stale training data**
   - It takes a long time to train an LLM and that means that the information they learn is often several years old.
3. **Lack of private data**
   - Asking questions about the news is one thing, but LLMs don't know anything about private data.

WHAT IS RAG?

(HINT: NOT CLOTH)

R•A•G | rag

noun

1. Acronym for **Retrieval-Augmented Generation**, a technique for enhancing the accuracy, utility, and timeliness of Large Language Models (LLMs).

2. A terrible name that the authors of the paper that coined it have said they regret.

***Abstract*—The *k*-nearest neighbor (*k*NN) classification has been widely adopted in data mining applications. In the age of big data, *k*NN classification process has to be outsourced to the cloud. However, as data may contain sensitive information, outsourcing data services directly to public clouds inevitably raises privacy concerns. To ensure the privacy of data, it is a well-known method to encrypt them prior to uploading to the cloud, which also brings great challenges to effective *k*NN classification. Homomorphic encryption (HE) allows operations on**

to the data records in the training set. Then the query record is classified by a majority vote of its nearest neighbors. Therefore, it is one of the most fundamental functionalities for big data analytics, and can widely be used in many data mining applications. Especially in the big data age, data centers may host the *k*NN classification services. As a feasible solution, outsourcing *k*NN classification process to the commercial public clouds is an economical option for small enterprises.

$\mathbf{m} \leftarrow \frac{\mathbf{c} - \lambda_{\mathbf{m}}}{s}$
return $\mathbf{m}$

HOW IT **WORKS**

Scale and Perturb (SAP)

Algorithm 2. The SAP scheme.

procedure $\mathcal{K}eyGen_{\mathsf{SAP}}()$
$s \xleftarrow{\$} \mathsf{S}$
$K \xleftarrow{\$} \{0,1\}^k$
return (s, K)

procedure $\mathcal{E}nc_{\mathsf{SAP}}((s, K), \mathbf{m})$
$n \xleftarrow{\$} \{0,1\}^\ell$
$\mathsf{coin}_1 \| \mathsf{coin}_2 \leftarrow \mathsf{PRF}(K, n)$
$\mathbf{u} \leftarrow \mathcal{N}(0, I_d; \mathsf{coin}_1)$
$x' \leftarrow \mathcal{U}(0, 1; \mathsf{coin}_2)$
$x \leftarrow \frac{s\beta}{4}(x')^{\frac{1}{d}}$; $\lambda_{\mathbf{m}} \leftarrow \frac{\mathbf{u}x}{\|\mathbf{u}\|}$
$\mathbf{c} \leftarrow s\mathbf{m} + \lambda_{\mathbf{m}}$
return $(\mathbf{c}, n)$

procedure $\mathcal{D}ec_{\mathsf{SAP}}((s, K), (\mathbf{c}, n))$
$\mathsf{coin}_1 \| \mathsf{coin}_2 \leftarrow \mathsf{PRF}(K, n)$
$\mathbf{u} \leftarrow \mathcal{N}(0, I_d; \mathsf{coin}_1)$
$x' \leftarrow \mathcal{U}(0, 1; \mathsf{coin}_2)$
$x \leftarrow \frac{s\beta}{4}(x')^{\frac{1}{d}}$
$\lambda_{\mathbf{m}} \leftarrow \frac{\mathbf{u}x}{\|\mathbf{u}\|}$
$\mathbf{m} \leftarrow \frac{\mathbf{c} - \lambda_{\mathbf{m}}}{s}$
return $\mathbf{m}$

- Plaintext vector is multiplied by secret key (***s***) then each attribute is adjusted up/down by some amount.
- Rough scale of perturbment (**K**) is random and stored as a component of the key.
- There's a per-vector random "IV" (***n***) so no two vectors are encrypted the same. This is needed to decrypt.
- Perturbation (***λ***) amount depends on ***β*** with higher bit security for higher ***β***.
- Per-attribute perturbation depends on a gaussian distribution and so is different for every attribute with different distributions for every encrypted vector.

HOW IT **WORKS**

Scale and Perturb (SAP)

Algorithm 2. The SAP scheme.

procedure $\mathcal{K}eyGen_{\mathsf{SAP}}()$
$s \xleftarrow{\$} \mathsf{S}$
$K \xleftarrow{\$} \{0,1\}^k$
return (s, K)

procedure $\mathcal{E}nc_{\mathsf{SAP}}((s, K), \mathbf{m})$

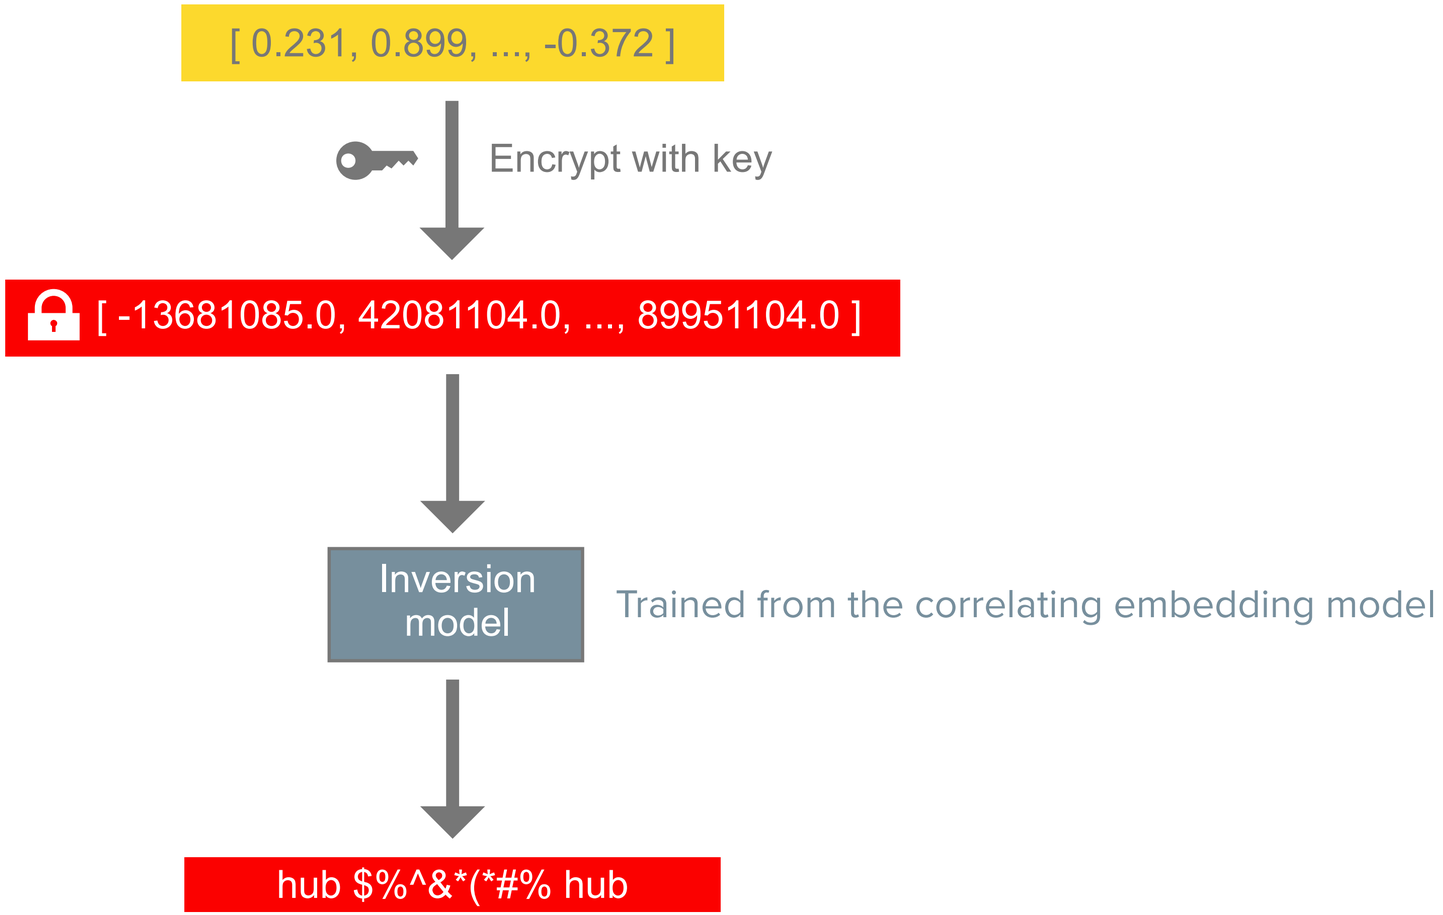
ATTACK ENCRYPTED VECTORS

Using an inversion model trained on the embedding model outputs



ATTACK ENCRYPTED VECTORS

Using an inversion model trained on the encrypted data

Using a Chosen Plaintext Attack

Assume: We can query an oracle and for any given plaintext, we can get back the corresponding ciphertext.

Given: We use these corresponding values to train an inversion model that's specific to the key used by the oracle.

Question: What results do we get?

ATTACK ENCRYPTED VECTORS

Using an inversion model trained on the encrypted data

Using a Chosen Plaintext Attack

Answer: It depends on the approximation factor, but the jitteriness of the encrypted values makes the results fall somewhere between "right general idea or theme of text with wrong specifics" to "laughably far off the mark".

ATTACK ENCRYPTED VECTORS

Bit security / chosen plaintext key recovery

Using a Chosen Plaintext Attack

Question: Given an associated plaintext vector and encrypted vector **and the IV** for that vector, can we figure out the key?

Answer: No

The key is protected by the PRF(K, n) function. Even knowing n, we'd have to exhaustively check all possible values of K in a brute force attack to find the key. **In ironcore-alloy, K is 256 bits.**

---

procedure $\mathcal{D}ec_{\mathsf{SAP}}((s, K), (\mathbf{c}, n))$
$\mathsf{coin}_1 \| \mathsf{coin}_2 \leftarrow \mathsf{PRF}(K, n)$
$\mathbf{u} \leftarrow \mathcal{N}(0, I_d; \mathsf{coin}_1)$
$x' \leftarrow \mathcal{U}(0, 1; \mathsf{coin}_2)$
$x \leftarrow \frac{s\beta}{4}(x')^{\frac{1}{d}}$
$\lambda_{\mathbf{m}} \leftarrow \frac{\mathbf{u}x}{\|\mathbf{u}\|}$
$\mathbf{m} \leftarrow \frac{\mathbf{c} - \lambda_{\mathbf{m}}}{s}$
return $\mathbf{m}$

SUMMARY

- Vectors are approximate copies of data which hold substantially all of the original information
- RAG and vectors are ripe for attacks and the attacks are not difficult.
- New vector databases are super weak on security.
- You can encrypt vectors and then it doesn't matter if you store them with a 3rd party
- The encryption isn't "ideal" and hasn't been attacked much yet, but adoption of AI systems using unencrypted vectors is soaring.
